Linear algebra in lattices, the Fitting lemma

Jenő Szigeti

Abstract. Lattice theoretical generalizations of some classical linear algebra results are formulated. A vector space is replaced by its subspace lattice and a linear map is replaced by the induced lattice map. This map is a complete join homomorphism and satisfies some additional natural conditions. The object of our study is a pair consisting of a complete lattice and one of its complete join endomorphisms. We prove the Fitting lemma for such a pair.

1. PRELIMINARIES

The purpose of this paper is to develop linear algebra for a pair (L, λ) satisfying some of the so called JNB conditions, here $(L, \vee, \wedge, 0, 1)$ is a complete lattice and $\lambda : L \longrightarrow L$ is a complete $\vee$-homomorphism with $\lambda(0) = 0$. A lattice theoretical Jordan normal base theorem for a nilpotent λ was proved in [3]. In the present work we continue the investigations started in [3], to provide a self contained treatment, we repeat the proof of a lemma which we need from [3].
Let R be a ring and $\varphi : M \longrightarrow M$ an R-endomorphism of the unitary left R-module ${}_RM$ (a vector space together with a linear map also can be considered). For a submodule $N \leq M$ let $\varphi(N) = \{\varphi(x) \mid x \in N\}$ denote the φ-image of N. Clearly, $\varphi(N) \leq M$ is an R-submodule and for any family N_γ, $\gamma \in \Gamma$ of R-submodules in M we have

$$\varphi\left(\sum_{\gamma\in\Gamma} N_\gamma\right) = \sum_{\gamma\in\Gamma} \varphi(N_\gamma).$$

If $X, Y \leq M$ are R-submodules with $X \subseteq Y$ and $\varphi(X) = \varphi(Y)$, then

$$X + (Y \cap \ker(\varphi)) = Y$$

and $\varphi(Y \cap \ker(\varphi)) = \{0\}$ holds for the R-submodule $Y \cap \ker(\varphi) \leq M$.
If $X \leq M$ is an R-submodule with $X \subseteq \varphi(N)$, then $\varphi^{-1}(X) = \{u \in M \mid \varphi(u) \in X\}$ and we have $\varphi(Z) = X$ for the R-submodule $Z = N \cap \varphi^{-1}(X) \subseteq N$ of M.
The above observations were used in [3] to formulate the so called JNB2 and JNB3 properties of the map λ (or of the pair (L, λ)), where

$$L = \mathrm{Sub}({}_RM)$$

1991 *Mathematics Subject Classification.* 06B23, 06C10, 15A21, 16D60.
Key words and phrases. complete lattice, complete join homomorphism, JNB conditions, semisimple module.

is the complete (and modular) lattice of the R-submodules of M with respect to the containment relation $\subseteq$ and

$$\lambda(N) = \varphi(N)$$

is the induced $L \longrightarrow L$ complete $\vee$-homomorphism (we note that $\bigvee\limits_{\gamma\in\Gamma} N_\gamma = \sum\limits_{\gamma\in\Gamma} N_\gamma$).

2. FINITE ATOMIC BASE IN A LATTICE

Let $(L, \vee, \wedge, 0, 1)$ be a lattice with $\leq_L$ ($<_L$) being the induced (strict) partial order on L. A finite set $\{a_i \mid 1 \leq i \leq n\}$ of atoms in L is called *independent*, if

$$a_{\pi(1)} <_L a_{\pi(1)} \vee a_{\pi(2)} <_L ... <_L a_{\pi(1)} \vee a_{\pi(2)} \vee ... \vee a_{\pi(n)}$$

is a strictly ascending chain for some permutation π of $\{1, 2, ..., n\}$. An *atomic base* of L is an independent set of atoms $\{a_i \mid 1 \leq i \leq n\}$ with $a_1 \vee a_2 \vee ... \vee a_n = 1$.
If $1 \in L$ is a join of atoms and $1 = b_1 \vee b_2 \vee ... \vee b_m$, ($b_1, b_2, ..., b_m$ are atoms in L) with m being the smallest possible, then $b_1 \vee b_2 \vee ... \vee b_m$ is an irredundant join and

$$b_{\sigma(1)} <_L b_{\sigma(1)} \vee b_{\sigma(2)} <_L ... <_L b_{\sigma(1)} \vee b_{\sigma(2)} \vee ... \vee b_{\sigma(m)}$$

is strictly ascending for any choice of the permutation σ of $\{1, 2, ..., m\}$. Thus $\{b_i \mid 1 \leq i \leq m\}$ is an atomic base of L.
The following trivial statement about the join of atoms is already present in [3].

2.1.Proposition. *Let $(L, \vee, \wedge, 0)$ be a lattice with the following properties.*
(i) *The cover relation $x \lhd x \vee a$ holds for all $x \in L$ and for all atoms $a \in L$ with $x \neq x \vee a$ (atomic cover property, it is satisfied in upper semimodular lattices).*
(ii) *Any two composition series of the form*

$$0 = x_0 \lhd x_1 \lhd ... \lhd x_n \text{ and } 0 = y_0 \lhd y_1 \lhd ... \lhd y_m$$

with $x_n = y_m$ are of the same length: $n = m$.
If $\{a_i \mid 1 \leq i \leq n\}$ is an independent set of atoms in L, then $a_1 \vee a_2 \vee ... \vee a_n$ is an irredundant join (or equivalently

$$a_1 \vee a_2 \vee ... \vee a_n = a_1 \oplus a_2 \oplus ... \oplus a_n$$

is a direct sum).

Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism with $\lambda(0) = 0$. The *image* and the *kernel* of λ can be defined as follows:

$$w = \mathrm{im}(\lambda) = \lambda(1) \text{ and } z = \ker(\lambda) = \vee\{x \in L \mid \lambda(x) = 0\}.$$

Clearly, the $\vee$-property of λ ensures that $\lambda(x) \leq_L \lambda(1) = w$ for all $x \in L$ and that $\lambda(x) = 0 \Longleftrightarrow x \leq_L z$.
Now we repeat the formulation of the properties (mentioned in the introduction) of the induced map $N \longmapsto \varphi(N)$ in the language of lattices. We keep the notations JNB2 and JNB3 of [3].

JNB2: For any choice of the elements $x \leq_L y$ with $\lambda(x) = \lambda(y)$ we can find an element $u \in L$ such that $y = x \vee u$ and $\lambda(u) = 0$.

JNB3: For any $x \in L$ the map $\lambda : [0, x] \longrightarrow [0, \lambda(x)]$ is surjective.

2.2.Lemma. *If every element of L is a join of atoms and λ satisfies JNB3, then any atom $a \in [0, \lambda(1)]$ can be written as $a = \lambda(a^*)$, where $a^* \in L$ is an atom.*

Proof. Since $\lambda : [0,1] \longrightarrow [0,\lambda(1)]$ is surjective, we can find an element $x \in L$ with $a = \lambda(x)$. Now we have $x = \vee\{b_i \mid i \in I\}$, where each $b_i \in L$ is an atom. Clearly, $b_i \leq_L x$ implies that $0 \leq_L \lambda(b_i) \leq_L \lambda(x) = a$. For an index $i \in I$, we have either $\lambda(b_i) = 0$ or $\lambda(b_i) = a$. If $\lambda(b_i) = 0$ holds for all $i \in I$, then we obtain

$$a = \lambda(x) = \lambda(\underset{i\in I}{\vee} b_i) = \underset{i\in I}{\vee}\lambda(b_i) = 0,$$

a contradiction. Thus $\lambda(b_j) = a$ holds for some $j \in I$.□

2.3.Proposition. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism such that $\lambda(0) = 0$. Consider the interval sublattices $[0, w]$ and $[0, z]$ of L with $w = \mathrm{im}(\lambda)$ and $z = \ker(\lambda)$.*
If $\{b_j \mid 1 \leq j \leq q\}$ is independent set of atoms in $[0, z]$ and $\{a_i \mid 1 \leq i \leq p\}$ is a set of atoms in L such that $\{\lambda(a_i) \mid 1 \leq i \leq p\}$ is an independent set of atoms (in $[0, w]$), then

$$\{b_j \mid 1 \leq j \leq q\} \cup \{a_i \mid 1 \leq i \leq p\}$$

is independent in L.
If λ satisfies JNB2, $b_1 \vee b_2 \vee ... \vee b_q = z$ and $\lambda(a_1) \vee \lambda(a_2) \vee ... \vee \lambda(a_p) = \lambda(1)$, then

$$b_1 \vee b_2 \vee ... \vee b_q \vee a_1 \vee a_2 \vee ... \vee a_p = 1,$$

i.e. $\{b_j \mid 1 \leq j \leq q\} \cup \{a_i \mid 1 \leq i \leq p\}$ is an atomic base of L.

Proof. Now we have strictly ascending chains

$$b_{\alpha(1)} <_L b_{\alpha(1)} \vee b_{\alpha(2)} <_L ... <_L b_{\alpha(1)} \vee b_{\alpha(2)} \vee ... \vee b_{\alpha(q)} = b$$

in $[0, z]$ and

$$\lambda(a_{\beta(1)}) <_L \lambda(a_{\beta(1)}) \vee \lambda(a_{\beta(2)}) <_L ... <_L \lambda(a_{\beta(1)}) \vee \lambda(a_{\beta(2)}) \vee ... \vee \lambda(a_{\beta(p)})$$

in $[0, w]$. We claim that

$$b <_L b \vee a_{\beta(1)} <_L b \vee a_{\beta(1)} \vee a_{\beta(2)} <_L ... <_L b \vee a_{\beta(1)} \vee a_{\beta(2)} \vee ... \vee a_{\beta(p)}$$

is also strictly ascending. Indeed $1 \leq i \leq p$ and

$$b \vee a_{\beta(1)} \vee a_{\beta(2)} \vee ... \vee a_{\beta(i-1)} = b \vee a_{\beta(1)} \vee a_{\beta(2)} \vee ... \vee a_{\beta(i)}$$

would imply that

$$a_{\beta(i)} \leq_L b \vee a_{\beta(1)} \vee a_{\beta(2)} \vee ... \vee a_{\beta(i-1)}.$$

Since $b \in [0, z]$ ensures that $\lambda(b) = 0$, the $\vee$-property of λ gives that

$$\lambda(a_{\beta(i)}) \leq_L \lambda(b) \vee \lambda(a_{\beta(1)}) \vee \lambda(a_{\beta(2)}) \vee ... \vee \lambda(a_{\beta(i-1)}) =$$
$$= \lambda(a_{\beta(1)}) \vee \lambda(a_{\beta(2)}) \vee ... \vee \lambda(a_{\beta(i-1)}),$$

whence

$$\lambda(a_{\beta(1)}) \vee ... \vee \lambda(a_{\beta(i-1)}) = \lambda(a_{\beta(1)}) \vee ... \vee \lambda(a_{\beta(i-1)}) \vee \lambda(a_{\beta(i)})$$

follows, a contradiction.
If $\lambda(a_1) \vee \lambda(a_2) \vee ... \vee \lambda(a_p) = \lambda(1)$, then we have

$$\lambda(a_1 \vee a_2 \vee ... \vee a_p) = \lambda(1)$$

and JNB2 implies that

$$(a_1 \vee a_2 \vee ... \vee a_p) \vee u = 1$$

holds for some $u \in L$ with $\lambda(u) = 0$. Since $u \leq_L z$, we have

$$b_1 \vee b_2 \vee ... \vee b_q \vee a_1 \vee a_2 \vee ... \vee a_p = z \vee (a_1 \vee a_2 \vee ... \vee a_p) = 1$$

proving that $\{b_j \mid 1 \leq j \leq q\} \cup \{a_i \mid 1 \leq i \leq p\}$ is an atomic base of L.□

2.4.Theorem. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism with $\lambda(0) = 0$ such that λ satisfies JNB2 and JNB3. Assume that every element of L is a join of atoms and consider the interval sublattices $[0, w]$ and $[0, z]$ of L with $w = \mathrm{im}(\lambda)$ and $z = \ker(\lambda)$. If $[0, w]$ has a p element atomic base and $[0, z]$ has a q element atomic base, then we can find a $p+q$ element atomic base in L.*

Proof. If $\{c_i \mid 1 \leq i \leq p\}$ is a p element atomic base of $[0, w]$, then Lemma 2.2 ensures the existence of atoms $a_i \in L$, $1 \leq i \leq p$ such that $\lambda(a_i) = c_i$ for all $1 \leq i \leq p$. Take a q element atomic base $\{b_j \mid 1 \leq j \leq q\}$ of $[0, z]$, then $\{b_j \mid 1 \leq j \leq q\} \cup \{a_i \mid 1 \leq i \leq p\}$ is a $p + q$ element atomic base of L by Proposition 2.3.□

Remark. Theorem 2.4 is the generalization of the well known

$$\dim(\mathrm{im}\varphi) + \dim(\ker \varphi) = \dim V$$

property of the linear map $\varphi : V \longrightarrow V$.

3. THE FITTING LEMMA

3.1.Proposition. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda_1, \lambda_2 : L \longrightarrow L$ complete $\vee$-homomorphisms with $\lambda_1(0) = \lambda_2(0) = 0$. Then $\lambda_1 \circ \lambda_2 : L \longrightarrow L$ is a complete $\vee$-homomorphisms with $(\lambda_1 \circ \lambda_2)(0) = 0$ and we have the following implications.*

1. *If λ_1 and λ_2 satisfy JNB3, then $\lambda_1 \circ \lambda_2$ satisfies JNB3.*
2. *If λ_1 satisfies JNB2, λ_2 satisfies JNB2 and JNB3, then $\lambda_1 \circ \lambda_2$ satisfies JNB2.*
3. *If λ_1 and λ_2 both satisfy JNB2 and JNB3, then $\lambda_1 \circ \lambda_2$ satisfies JNB2 and JNB3.*

Proof.
1. If $x \in L$, then $\lambda_2 : [0, x] \longrightarrow [0, \lambda_2(x)]$ and $\lambda_1 : [0, \lambda_2(x)] \longrightarrow [0, \lambda_1(\lambda_2(x))]$ are surjective maps, thus their composition $\lambda_1 \circ \lambda_2 : [0, x] \longrightarrow [0, \lambda_1(\lambda_2(x))]$ is also surjective.
2. If $x \leq_L y$ and $\lambda_1(\lambda_2(x)) = \lambda_1(\lambda_2(y))$ holds for $x, y \in L$, then $\lambda_2(x) \leq_L \lambda_2(y)$ and JNB2 of λ_1 gives an element $u \in L$ such that $\lambda_2(y) = \lambda_2(x) \vee u$ and $\lambda_1(u) = 0$. Now $u \in [0, \lambda_2(y)]$ and JNB3 of λ_2 gives an element $v \in [0, y]$ such that $\lambda_2(v) = u$. In view of $x \vee v \leq_L y$ and

$$\lambda_2(x \vee v) = \lambda_2(x) \vee \lambda_2(v) = \lambda_2(x) \vee u = \lambda_2(y)$$

JNB2 of λ_2 gives an element $w \in L$ such that $(x \vee v) \vee w = y$ and $\lambda_2(w) = 0$. Thus $x \vee (v \vee w) = y$ and

$$\lambda_1(\lambda_2(v \vee w)) = \lambda_1(\lambda_2(v) \vee \lambda_2(w)) = \lambda_1(u \vee 0) = \lambda_1(u) = 0$$

prove the JNB2 property of $\lambda_1 \circ \lambda_2$.□

3.2.Corollary. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism with $\lambda(0) = 0$. If λ satisfies JNB2 and JNB3, then any power λ^k satisfies JNB2 and JNB3.*

3.3.Proposition. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism with $\lambda(0) = 0$. We have the following implications.*

(1) $\mathrm{im}(\lambda^k) = \mathrm{im}(\lambda^{k+1})$ *implies that* $\mathrm{im}(\lambda^i) = \mathrm{im}(\lambda^k)$ *for all integers* $i \geq k$.
(2) $\ker(\lambda^k) = \ker(\lambda^{k+1})$ *implies that* $\ker(\lambda^i) = \ker(\lambda^k)$ *for all integers* $i \geq k$.
(3) *If* λ *satisfies JNB2, then* $\mathrm{im}(\lambda) = \mathrm{im}(\lambda^2)$ *implies that* $\mathrm{im}(\lambda) \vee \ker(\lambda) = 1$.
(4) *If* λ *satisfies JNB3, then* $\ker(\lambda) = \ker(\lambda^2)$ *implies that* $\mathrm{im}(\lambda) \wedge \ker(\lambda) = 0$.

Proof.
1. Clearly, $\lambda^k(1) = \lambda^{k+1}(1)$ implies that $\lambda^{k+1}(1) = \lambda^{k+2}(1)$.
2. Take $x = \ker(\lambda^{k+2})$, then $\lambda^{k+1}(\lambda(x)) = \lambda^{k+2}(x) = 0$ implies $\lambda(x) \leq_L \ker(\lambda^{k+1})$, whence $\lambda(x) \leq_L \ker(\lambda^k)$ can be obtained. Thus $x \leq_L \ker(\lambda^{k+1})$ is a consequence of $\lambda^{k+1}(x) = \lambda^k(\lambda(x)) = 0$. Since $\ker(\lambda^{k+1}) \leq_L \ker(\lambda^{k+2})$ is obvious, we get $\ker(\lambda^{k+1}) = \ker(\lambda^{k+2})$.
3. Using $w = \mathrm{im}(\lambda) = \lambda(1)$ and $z = \ker(\lambda)$, we have

$$\lambda(w \vee z) = \lambda(w) \vee \lambda(z) = \lambda(\lambda(1)) \vee 0 = \lambda^2(1) = \lambda(1).$$

The JNB2 property of λ gives that $(w \vee z) \vee u = 1$ and $\lambda(u) = 0$ for some $u \in L$. Thus $u \leq_L z$ and $w \vee z = (w \vee z) \vee u = 1$.
4. Take $y = \mathrm{im}(\lambda) \wedge \ker(\lambda)$, then $y \leq_L \lambda(1)$ and thus $y \in [0, \lambda(1)]$. The JNB3 property of λ ensures the existence of an element $v \in L$ such that $\lambda(v) = y$. Now $y \leq_L \ker(\lambda)$ implies that $\lambda^2(v) = \lambda(y) = 0$, whence $v \leq_L \ker(\lambda^2)$ can be derived. Since $\ker(\lambda^2) = \ker(\lambda)$, we have $y = \lambda(v) = 0$.□

3.4.Theorem. *Let $(L, \vee, \wedge, 0, 1)$ be a complete lattice and $\lambda : L \longrightarrow L$ a complete $\vee$-homomorphism with $\lambda(0) = 0$ such that λ satisfies JNB2 and JNB3. If L is both Artinian and Noetherian (or L is of finite height), then there exists an integer $r \geq 1$ such that $\mathrm{im}(\lambda^r) \oplus \ker(\lambda^r) = 1$ (i.e. $\mathrm{im}(\lambda^r) \vee \ker(\lambda^r) = 1$ and $\mathrm{im}(\lambda^r) \wedge \ker(\lambda^r) = 0$).*

Proof. The Artinian condition ensures that

$$\mathrm{im}(\lambda) \geq_L \mathrm{im}(\lambda^2) \geq_L \ldots \geq_L \mathrm{im}(\lambda^i) \geq_L \ldots$$

is not a strictly descending chain, thus $\mathrm{im}(\lambda^k) = \mathrm{im}(\lambda^{k+1})$ holds for some integer $k \geq 1$.
The Noetherian condition ensures that

$$\ker(\lambda) \leq_L \ker(\lambda^2) \leq_L \ldots \leq_L \ker(\lambda^i) \leq_L \ldots$$

is not a strictly ascending chain, thus $\ker(\lambda^l) = \ker(\lambda^{l+1})$ holds for some integer $l \geq 1$.
Take $r = \max\{k, l\}$, then

$$\mathrm{im}(\lambda^r) = \mathrm{im}(\lambda^{2r}) \text{ and } \ker(\lambda^r) = \ker(\lambda^{2r})$$

by part 1 and part 2 of Proposition 3.3, respectively. In view of Corollary 3.2, the power λ^r satisfies JNB2 and JNB3. Since $\lambda^{2r} = (\lambda^r)^2$, the application of part 3 and part 4 of Proposition 3.3 give that $\mathrm{im}(\lambda^r) \vee \ker(\lambda^r) = 1$ and $\mathrm{im}(\lambda^r) \wedge \ker(\lambda^r) = 0$.□

Remark. Theorem 3.4 is the generalization of the well known Fitting lemma. We note that a completely different lattice theoretical Fitting lemma can be found in [2], it can be considered as an analogue and not a generalization of the classical result.
